

■ General Description

The AME6602 is an integrated power switch for self-powered and bus-powered Universal Serial Bus (USB) application. The AME6602 has several protections features such as current limiting and thermal shutdown to prevent catastrophic switch failure caused by increasing power dissipation when continuous heavy loads or short circuit occurs. A built-in P-channel MOSFET used for power MOS has superior R_{on} and easy control characteristics. The output reverse-current protection turns off the MOSFET switch whenever occurs the unexpected continuously reverse current. \overline{FLAG} pin is an open-drain output report overcurrent or over-temperature event and has typical 8ms deglitch timeout period. AME6602 is available in SOT-25, TSOT-25A, TSOT-26A, MSOP-8 & DFN-6D(2x2x0.75mm) packages.

■ Features

- Operating Range: 2.7V to 5.5V
- 75m Ω (Typ.) High-Side MOSFET
- Constant Current during Over-Current and Current Limit with Fold-Back are Available
- Active High or Active Low Version is Available
- 1.4ms Rise Time at $V_{IN} = 3.3V$ Condition
- Fast Short-Circuit Response: 1.5 μ S(Typ.)
- Under Voltage Lockout, Over-Current, Output-Voltage and Thermal Protection
- Deglitched Open-Drain Flag Output (\overline{FLAG})
- UL Certification-File No. E529690

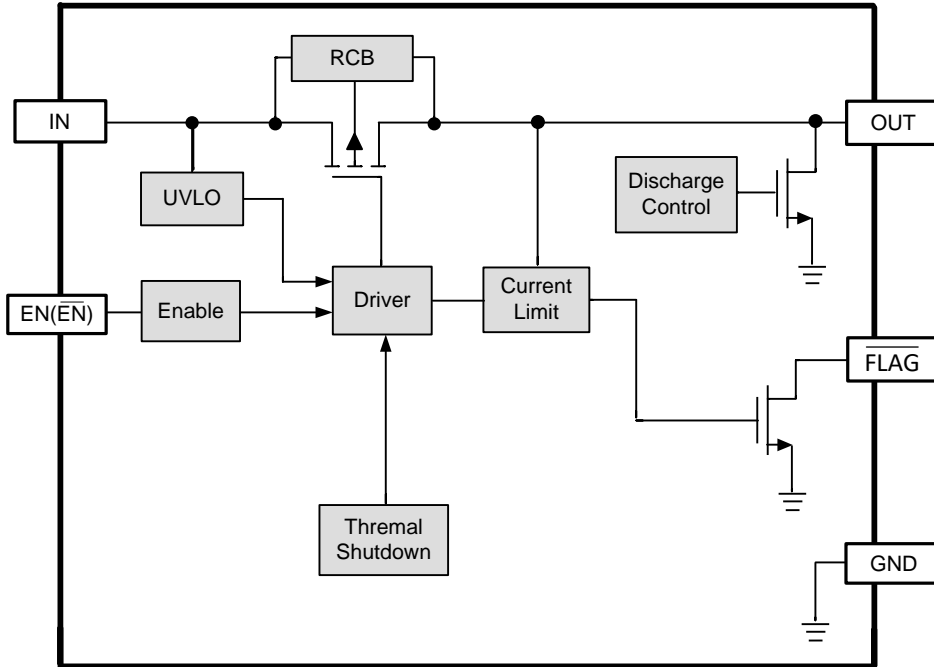

■ Application

- Laptops, Desktops, AIO
- Set-Top Boxes
- LCD TVs & Monitors
- Residential Gateways
- e-Readers, Printers, Hubs
- Docking, HUB

■ Application Information

Supply Filtering

A 1 μ F bypass capacitor from IN to GND, placed near the AME6602, is strongly recommended to control supply transients. Without a bypass capacitor, an output short may cause sufficient ringing on the input (from supply lead inductance) to damage internal control circuitry. Input transients must not exceed the absolute maximum supply voltage ($V_{IN\ max} = 6V$) even for a short duration.

ON and OFF Control

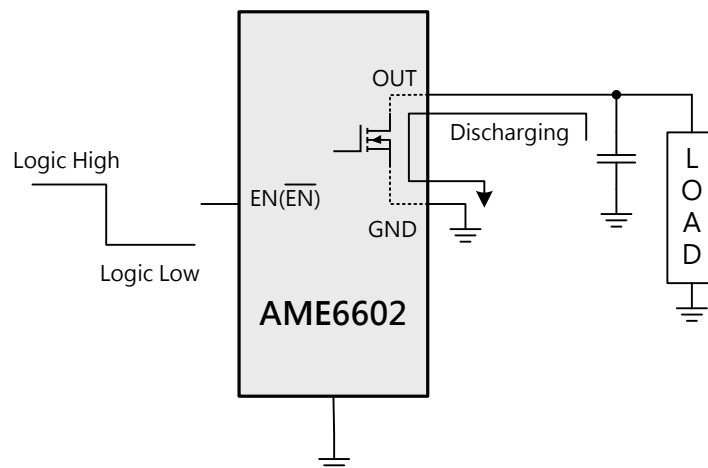

EN(\overline{EN}) must be driven logic high or logic low for a clearly defined input. Floating the input may cause unpredictable operation. The pin should not be allowed to go negative with respect to GND.

Auto Output Discharge

The discharge function is activated when EN(\overline{EN}) pin is disabled or de-asserted. The power switch automatically offers a resistive discharge path for the external storage capacitor. This facilitates discharging any residue of the output voltage when either no external output resistance or load resistance is present at the output.

EN	IN to OUT	OUT to GND
H	ON	OFF
L	OFF	ON

\overline{EN}	IN to OUT	OUT to GND
H	OFF	ON
L	ON	OFF

■ Application Information (Contd.)

FLAG Indicator

The FLAG open-drain output is asserted (FLAG: active low) during an over-current or over-temperature condition. Until the fault condition is de-asserted and the AME6602 resumes normal operation. The AME6602 eliminate false FLAG reporting by using an internal delay "deglitch" circuit for over-current (8ms typ.) conditions without the need for external circuitry. This ensures that FLAG is not accidentally asserted due to normal operation such as starting into a heavy capacitive load.

Power Dissipation

Thermal analysis is strongly dependent on additional system level factors such as air flow, board layout, copper thickness and surface area, and proximity to other devices dissipating power.

Good thermal design practice must include all system level factors in addition to individual component analysis. Begin by determining the $R_{DS(ON)}$ of the internal MOSFET relative to the input voltage and operating temperature. As an initial estimate, make use of the highest operating ambient temperature of interest and read $R_{DS(ON)}$ from the typical characteristics graph. Using this value, the power dissipation can be calculated by:

$$P_D = R_{DS(ON)} \times (I_{OUT})^2$$

Where:

P_D = Total power dissipation (W)

$R_{DS(ON)}$ = MOSFET on-resistance (Ω)

I_{OUT} = Maximum current-limit threshold (A)

This step calculates the total power dissipation of internal MOSFET.

Next, the junction temperature of the device depends on different contributing factors such as board layout, ambient temperature, device environment, and so on. Then, calculate the junction temperature:

$$T_J = P_D \times \theta_{JA} + T_A$$

Where:

T_A = Ambient temperature ($^{\circ}\text{C}$)

θ_{JA} = Thermal resistance ($^{\circ}\text{C}/\text{W}$)

P_D = Total power dissipation (W)

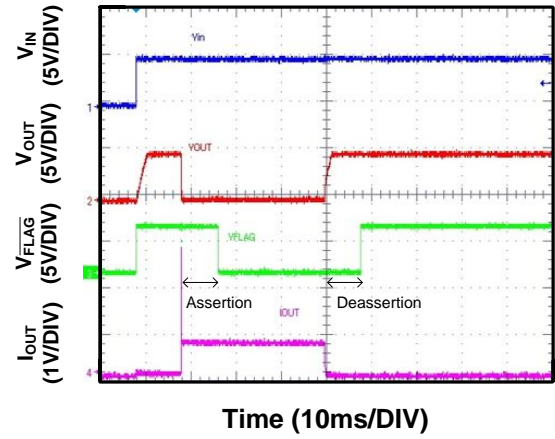

Compare the calculated T_J with the initial estimate. If they are not within a few degrees, repeat the calculation using the refined $R_{DS(ON)}$ from the previous calculation as the new estimate. Two or three iterations are generally sufficient to achieve the desired result. The final T_J is highly dependent on θ_{JA} and thermal resistance is respectably dependent on the individual package and board layout.
